

README

File location: `$VCS_HOME/doc/examples/nativetestbench/openvera/rvm/restart/hard/README`

This example shows how a verification environment can be restarted to perform two "tests" in sequence, resetting and reconfiguring the DUT between tests.

This simple approach would be used if it is necessary to minimize the time spent creating a simulatable image and starting the simulator. Because random stability is not considered in this example (see the "hard_stable" example), this approach would be suitable for tests that are likely to produce the same bug regardless of the seed used initially or that will not require stand-alone simulation to debug them.
